

# **L'Hôpital's (Selection) Rule**

## **An Empirical Bayes Application to French Hospitals**

Fu Zixuan

June 20, 2024

# Outline

Introduction

Data and Estimation

Empirical Bayes Compound decision: The Selection Problem

Conclusion

## Motivation: Invidious decision

- ▶ *League table mentality*: Ranking & Selection.
- ▶ *Noisy estimates*: Unobserved heterogeneity.
- ▶ *Bayesian view*: Prior distribution.

## Motivation: French Hospitals

- ▶ *Productivity/Efficiency*: Factories, Schools, Hospitals etc.
- ▶ *Methodology*:
  1. (Parametric) Stochastic Frontier  
[Aigner et al., 1977, Meeusen and van Den Broeck, 1977]→ How far it is to the frontier.
  2. (Non-Parametric): Data Envelopment [Charnes et al., 1978]→ Compare with other units.
  3. Input demand function: [Croiset and Gary-Bobo, 2024].
- ▶ *Ownership*: Public (Teaching, Ordinary) vs. Private (For profit, Non-profit).

## Questions

- ▶ Out of the top 20% hospitals in France<sup>1</sup>, how many of them are public hospitals/private hospitals?
- ▶ What would be the selection outcome if I also control for the **False Discovery Rate**?
- ▶ Does different ranking/selection rule produce contradicting results? And to what degree?

---

<sup>1</sup>in terms of labor (nurses) employment efficiency

# Roadmap

1. Data: The Annual Statistics of Health Establishments (SAE), from 2013 to 2022.
2. Estimation of efficiency
  - $Y$ : Labor input (number of full time equivalent nurses).
  - $X$ : Hospital output (e.g., inpatient/outpatient stays, medical sessions).
3. Selection problem: Compound decision framework and optimal decision rule
4. Comparison of outcomes under different decision rules
5. Conclusion

## Panel data Estimator

- ▶ Strict exogeneity: Within Group/First Difference

$$E[\epsilon_{it}|x_{i1}, \dots, x_{iT}, \theta_i] = 0$$

- ▶ Relaxed: First Difference GMM [Arellano and Bond, 1991], System GMM [Arellano and Bover, 1995, Blundell and Bond, 1998a].

$$E[\epsilon_{it}|x_{i1}, \dots, x_{it-p}, \theta_i] = 0$$

Issues: Weak instruments [Blundell and Bond, 1998b] and the proliferation of instruments [Roodman, 2007].

$$\mathbb{E}[\Delta x_{i,t-1}(y_{it} - \beta x_{it})] \quad \text{if} \quad \mathbb{E}[\Delta x_{i,t-1}(\theta_i + \varepsilon_{i,t})] = 0$$

# Outline

Introduction

Data and Estimation

Empirical Bayes Compound decision: The Selection Problem

Conclusion

# Compound Decision Framework

Observe:

$$\hat{\boldsymbol{\theta}} = (\hat{\theta}_1, \dots, \hat{\theta}_n)$$

$$\text{where } \hat{\theta}_i | \theta_i \sim P_{\theta_i}$$

Decision:

$$\delta(\hat{\boldsymbol{\theta}}) = (\delta_1(\hat{\boldsymbol{\theta}}), \dots, \delta_n(\hat{\boldsymbol{\theta}}))$$

## Compound Loss and Risk

Loss:

$$L_n(\theta, \delta(\hat{\theta})) = \sum_{i=1}^n L(\theta_i, \delta_i(\hat{\theta})).$$

Risk (Expectation of risk):

$$\begin{aligned} R_n(\theta, \delta(\hat{\theta})) &= \mathbb{E}[L_n(\theta, \delta(\hat{\theta}))] \\ &= \frac{1}{n} \sum_{i=1}^n \mathbb{E}[L(\theta_i, \delta_i(\hat{\theta}))] \\ &= \frac{1}{n} \sum_{i=1}^n \int \dots \int L(\theta_i, \delta_i(\hat{\theta}_1, \dots, \hat{\theta}_n)) dP_{\theta_1}(\hat{\theta}_1) \dots dP_{\theta_n}(\hat{\theta}_n). \end{aligned}$$

## The Selection Task

- ▶ Select the bottom 20% <sup>3</sup> out of the population of  $\theta_i$ , those  $i$  whose  $\alpha_i < G^{-1}(0.2)$
- ▶ Control the overall false discovery rate at 20%,

$$\frac{\mathbb{E}_G [1 \{ \theta_i > \theta_\alpha, \delta_i = 1 \}]}{\mathbb{E}_G [\delta_i]} \leq \gamma$$

---

<sup>3</sup>The most efficient 20%.

## Problem Formulation

The **loss** function is

$$L(\delta, \theta) = \sum h_i(1 - \delta_i) + \tau_1 \left( \sum (1 - h_i)\delta_i - \gamma\delta_i \right) + \tau_2 \left( \sum \delta_i - \alpha n \right)$$

Therefore, the problem is to find  $\delta$  such that

$$\begin{aligned} \min_{\delta} \quad & \mathbb{E}_G \mathbb{E}_{\theta|\hat{\theta}} [L(\delta, \theta)] \\ = & \mathbb{E}_G \sum \mathbb{E}(h_i)(1 - \delta_i) + \tau_1 \left( \sum (1 - \mathbb{E}(h_i))\delta_i - \gamma\delta_i \right) \\ & + \tau_2 \left( \sum \delta_i - \alpha n \right) \\ = & \mathbb{E}_G \sum v_{\alpha}(\hat{\theta})(1 - \delta_i) + \tau_1 \left( \sum (1 - v_{\alpha}(\hat{\theta}))\delta_i - \gamma\delta_i \right) + \tau_2 \left( \sum \delta_i - \alpha n \right) \end{aligned}$$

where  $v_{\alpha}(\hat{\theta}) = \mathbb{P}(\theta < \theta_{\alpha}|\hat{\theta})$  is the **posterior tail probability**.

## Prior Distribution $G$

Observe

$$Y_{it} = \theta_i + \varepsilon_{it} \quad \varepsilon_{it} \sim \mathcal{N}(0, \sigma_i^2) \quad (\theta_i, \sigma_i^2) \sim G$$

Neither  $\theta_i$  nor  $\sigma_i^2$  is known. But the sufficient statistics are

$$Y_i = \frac{1}{T_i} \sum_{t=1}^{T_i} Y_{it} \quad \text{where} \quad Y_i | \theta_i, \sigma_i^2 \sim \mathcal{N}(\theta_i, \sigma_i^2 / T_i)$$

$$S_i = \frac{1}{T_i - 1} \sum_{t=1}^{T_i} (Y_{it} - Y_i)^2 \quad \text{where} \quad S_i | \sigma_i^2 \sim \Gamma(r_i = (T_i - 1)/2, 2\sigma_i^2 / (T_i - 1))$$

## Tail probability

Given the two sufficient statistics, the posterior tail probability is

$$\begin{aligned} v_\alpha(Y_i, S_i) &= P(\theta_i > \theta_\alpha | Y_i, S_i) \\ &= \frac{\int_{-\infty}^{\theta_\alpha} \Gamma(s_i | r_i, \sigma_i^2) f(y_i | \theta_i, \sigma_i^2) dG(\theta_i, \sigma_i^2)}{\int_{-\infty}^{\infty} \Gamma(s_i | r_i, \sigma_i^2) f(y_i | \theta_i, \sigma_i^2) dG(\theta_i, \sigma_i^2)} \end{aligned}$$

We want to find a cutoff  $\lambda$  such that both constraints are satisfied <sup>4</sup>:

- Capacity:  $\int \int P(v_\alpha(Y_i, S_i) > \lambda) dG(\theta_i, \sigma_i^2) \leq \alpha$
- FDR:  $\int \int \frac{E[1\{v_\alpha(Y_i, S_i) > \lambda\}(1 - v_\alpha(Y_i, S_i))]}{E[1\{v_\alpha(Y_i, S_i) > \lambda\}]} dG(\theta_i, \sigma_i^2) \leq \gamma$

---

<sup>4</sup>Relaxed discrete optimization problem, following [Basu et al., 2018]

## Estimate $G$

Following [Koenker and Mizera, 2014] The primal problem:

$$\min_{f=dG} \left\{ - \sum_i \log g(y_i) \middle| g_i = T(f_i), K(f_i) = 1, \forall i \right\}$$

where  $T(f_i) = \int p(y|\alpha) f_i d\alpha$  and  $K(f_i) = \int f_i d\alpha$ .

Discretize the support:

$$\min_{f=dG} \left\{ - \sum_i \log g(y_i) \middle| g = Af, 1^T f = 1 \right\}$$

where  $A_{ij} = p(y_i|\alpha_j)$  and  $f = (f(\alpha_1), f(\alpha_2), \dots, f(\alpha_m))$ .

The dual problem:

$$\max_{\lambda, \mu} \left\{ \sum_i \log \lambda_1(i) \middle| A^T \lambda_1 < \lambda_2 1, (\lambda_1 > 0) \right\}$$

## The estimated $\hat{G}$

Case 1:  $\sigma_i$  unknown, only  $S_i$  observed.

Case 2:  $\sigma_i$  known.

## Unknown $\sigma_i$ : Posterior Tail probability

## Unknown $\sigma_i$ : Posterior Mean

## Known $\sigma_i$ : Posterior Tail probability

## Known $\sigma_i$ : Posterior Mean

## "Face value"

# Outline

Introduction

Data and Estimation

Empirical Bayes Compound decision: The Selection Problem

Conclusion

## Conclusion

- ▶ Difference in whether to assume known  $\sigma_i$ .
- ▶ Control for the False Discovery Rate.
- ▶ Private (FP and NP) hospitals are indeed more "efficient".

## Limitation

- ▶ Specification
- ▶ Endogeneity issue
- ▶ Normality assumption on  $\varepsilon_{it}$
- ▶ Interpretation of the  $\theta_i$ .

## Normality assumption on $\varepsilon_{it}$

Estimate the fixed effect  $\theta_i$  by

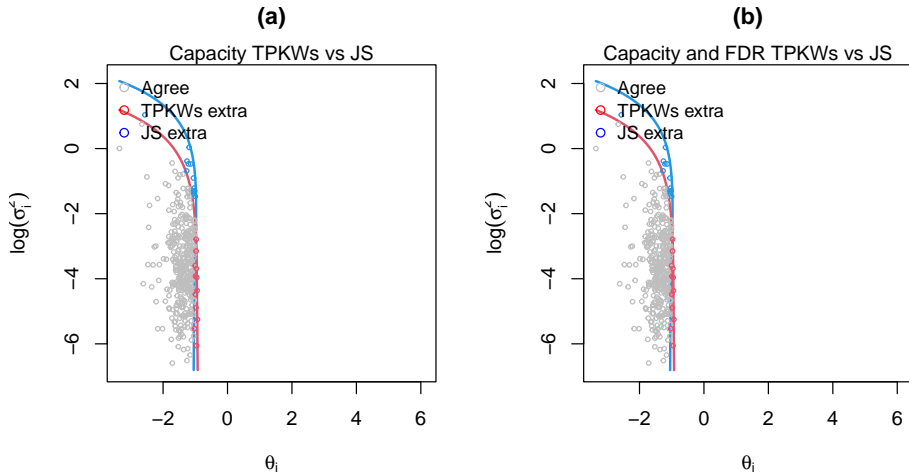

$$\hat{\theta}_i = \frac{1}{T} \sum (\theta_i + \varepsilon_{it} + x_{it}(\beta - \hat{\beta}))$$
$$\xrightarrow{N \rightarrow \infty} \theta_i + \frac{1}{T} \sum_t \varepsilon_{it}$$

When  $T$  is relatively small (or even fixed), can't use central limit theorem to claim that  $\hat{\theta}_i \xrightarrow{d} \mathcal{N}(\theta_i, \frac{\sigma_i^2}{T})$ .  $\longleftarrow$  Assume that  $\varepsilon_{it} \sim \mathcal{N}(0, \sigma_i^2)$ .
